

Name : JOGANI KRISH

Module 3 : Testing On Live Application

ASSIGNMENT - 3

1. What is RDBMS?

❖ RDBMS is Relational Database Management System is software that manage Relational databases, which store data in structured tables of rows and columns.

2. What is SQL?

❖ SQL is Structured Query Language is a domain specific programming language used for managing and manipulating relational databases.

3. Write SQL Commands?

1. Data Definition Language(DDL): CREATE, ALTER, DROP

2. Data Manipulation Language(DML): INSERT, DELETE, UPDATE

3. Data Control Language(DCL): GRANT, REVOKE, COMMIT, ROLLBACK,
SAVEPOINT

4. Data Query Language(DQL): SELECT

4. What is join?

- ❖ In SQL, a JOIN is a clause used to combine rows from two or more tables based on a related column between them.
- ❖ It allows you to retrieve data that is distributed across multiple tables and present it as a single, unified result set.

5. Write types of joins?

★ Common types of SQL JOINS:

- **INNER JOIN:** Returns only the rows that have matching values in both tables. Rows that do not have a match in both tables are excluded.

- **LEFT (OUTER) JOIN:** Returns all rows from the left table and the matching rows from the right table. If there is no match in the right table, Null values are returned for the right table's columns.
- **RIGHT (OUTER) JOIN:** Returns all rows from the right table and the matching rows from the left table. If there is no match in the left table, Null values are returned for the left table's columns.
- **FULL (OUTER) JOIN:** Returns all rows when there is a match in either the left or right table. If a row in one table has no match in the other, Null values are returned for the columns of the non-matching table.
- **CROSS JOIN:** Returns the Cartesian product of the two tables, meaning every row from the first table is combined with every row from the second table.
- **SELF JOIN:** A join used to join a table to itself, treating it as two separate tables. This is useful for finding relationships within the same table, such as hierarchical data.

6. How many constraints and describes itself?

❖ The most common types of constraints in SQL are:

- **NOT NULL:** Ensures that a column cannot have an empty value.
- **UNIQUE:** Guarantees that all values in a column or a set of columns are distinct.
- **PRIMARY KEY:** Uniquely identifies each row record in a table. It is a combination of NOT NULL and UNIQUE constraints, and each table can have only one primary key.
- **FOREIGN KEY:** Establishes a link and relationship between data in two tables by referencing the PRIMARY KEY of a parent table.
- **CHECK:** Enforces a specific condition or business rule that values in a column must satisfy.
- **DEFAULT:** Automatically assigns a default value to a column if no value is explicitly provided during INSERT operation.
- **CREATE INDEX:** Although often considered an object for performance optimization.

7.Difference between RDBMS vs DBMS?

Features	DBMS	RDBMS
Data Storage	Stores data in files e.g., hierarchical or navigational	Stores data in tables with rows and columns.
Data Relationships	Does not support relationships between files or data.	Uses primary and foreign keys to establish relationships between tables.
Normalization	Does not support data normalization.	Supports normalization to reduce data redundancy.
User Support	Typically supports a single user at a time.	Supports multiple users simultaneously.
Architecture	Does not support client-server architecture.	Supports the client-server architecture.
Data Integrity	Less secure and offers lower data integrity.	Higher data integrity and consistency through constraints and relationships.
Examples	Windows registry, XML.	SQL, MySQL, Oracle, PostgreSQL, Microsoft SQL Server

8.What is API Testing?

- ❖ API testing is a type of software testing that verifies the functionality, reliability, performance, and security of Application Programming Interfaces (APIs).
- ❖ APIs are the communication bridges that allow different software components, applications, or systems to interact and exchange data.

9.Types of API Testing?

There are 3 Main types of API Testing:

- 1. Open API Testing**
- 2. External API Testing**
- 3. Internal API Testing**

10. What is Responsive Testing?

- ❖ Responsive Testing is the process of checking if a website or app adapts correctly to various devices, screen sizes, and orientations to provide a seamless user experience.

11. Which types of tools are available for Responsive Testing?

- 1. Responsinator**
- 2. Screenfly**
- 3. Responsive Design Checker**
- 4. Viewport Resizer**
- 5. BrowserStack**
- 6. LambdaTest**
- 7. CrossBrowserTesting**

12. What is the full form of .ipa, .apk?

- 1. .ipa: Android Package Kit**
- 2. .apk: IOS App Store Package**

13. How to create a step to open the developer option mode ON?

★ Step-by-step guide

- 1. Open Settings:** Go to the main Settings app on your device.
- 2. Go to "About phone":** Scroll down and tap on About phone or About device.
- 3. Find "Build number":** You may need to tap on Software information or Android version to find it.
- 4. Tap "Build number" seven times:** Tap the Build number option rapidly seven times. You'll see a countdown appear after a few taps.
- 5. Enter your PIN or password:** If you have a lock screen, you'll be prompted to enter your pattern, PIN, or password to confirm.

6. Confirm and exit: A message will appear saying "You are now a developer!". You can now go back to the main Settings menu, and Developer options will be visible, often at the bottom or under a System menu.
